Morbidity and Mortality

Weekly Report

U. S. DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE PUBLIC HEALTH SERVICE

Prepared by the

COMMUNICABLE DISEASE CENTER

MElrose 4-5131

For release August 17, 1962

ATLANTA 22, GEORGIA

Vol. 11, No. 32

PROVISIONAL INFORMATION ON SELECTED NOTIFIABLE DISEASES IN THE UNITED STATES AND ON DEATHS IN SELECTED CITIES FOR WEEK ENDED AUGUST 11, 1962

POLIOMYELITIS - A total of 27 cases of poliomyelitis (21 paralytic) was reported in the nation for the week ending August 11. The decline from the 31 cases (24 paralytic) noted during the preceding week is extraordinary for the season. The comparable week in 1961 brought reports of 54 cases of poliomyelitis (36 paralytic).

Ten States accounted for the poliomyelitis reported this week. Texas, once again, submitted the largest number with 11 cases, including 7 paralytic. The paralytic cases in this State stemmed from six different counties with two from counties which have undertaken mass administration of oral polio-vaccine as an epidemic deterrent.

Of the remaining States, Michigan and Virginia each accounted for three cases. The Michigan cases represent delayed reports and originate from different counties. In Virginia, all three cases were from Washington County, with one from Bristol, Virginia, and two from the small town of Damascus. Further laboratory and epidemiologic studies are being performed in these cases.

The total number of reported cases of poliomyelitis thus far this year remains below the total for the similar period in any previous year. The number of paralytic cases, however, is the same as the number of paralytic cases in 1961. Cumulative totals through the 32nd week for 1962 and the previous four years is presented in the

Table 1. CASES OF SPECIFIED NOTIFIABLE DISEASES: UNITED STATES (Cumulative totals include revised and delayed reports through previous week)

Palia (Cumulated Weekly) Through the 32nd Week (1958-1962)

| | 1962 | 1961 | 1960 | 1959 | 1958 |
|-----------|------|------|------|------|------|
| Paralytic | 274 | 274 | 777 | 1892 | 716 |
| Tatal | 357 | 413 | 1074 | 2924 | 1457 |

HEPATITIS – The total of 728 reported cases of viral hepatitis for the current week continues the recent trend toward the low of 601 reached in the week ending July 6. No significant increase occurred in any of the States.

DIPHTHERIA - UNITED STATES, 1961

Individual case reports have been received at the Diphtheria Surveillance Unit, Communicable Disease Center, on 582 cases of diphtheria with onset of illness in 1961. Sixty of these cases were fatal. While the number of cases in 1961 is one-third below the 1960 total of 873, the 60 deaths reported in 1961 show little change from the 67 deaths in 1960.

There were no large-scale outbreaks of diphtheria in 1961. As in previous years, the diphtheria cases occurred predominantly during the fall and early winter. Three-fourths of the cases occurred in the Southern States with almost one-third of all cases from Texas alone. In the Northern States, north central Minnesota continues to demonstrate an endemic concentration of cases. The accompanying map (Figure I) shows the distribution of

diphtheria cases by State for those cases with onsets in 1961.

Attack rates for the non-white population in the United States were four times higher than in the white population. Nearly one-third (32.5 percent) of all diphtheria cases occurred in children under five years of age. No significant differences were found in distribution of cases by sex. The age distribution of cases and age specific attack rates are shown in Table I and Figure II.

TABLE I - DIPHTHERIA MORBIDITY BY RACE AND AGE - 1961

| Age Group | White | Non-White |
|-----------------|-------|-----------|
| 0 - 4 | 103 | 86 |
| 5 - 9 | 106 | 58 |
| 10 - 14 | 59 | 39 |
| 15 - 19 | 23 | 10 |
| 20 - 29 | 28 | 9 |
| 30 ⁺ | 46 | 9 |
| Unknown | 2 | 1 |
| Totals | 367 | 212 |

Three-fourths of the diphtheria cases had received no diphtheria immunizations. All but one of the deaths were in individuals who were inadequately immunized or had not been immunized. The one exception was a 1-year-old boy who died of diphtheria three months after completing a primary series; however, this boy had severe measles along with diphtheria. The immunization status and severity of illness for 423 cases on which information is available are shown in Table II.

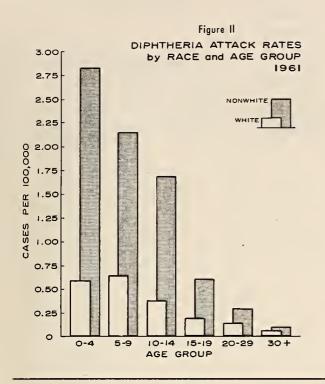

TABLE II - IMMUNIZATION STATUS

| 5everity of Illness | Full | Lopsed | Inadequate | None | Tata |
|------------------------|------|--------|------------|------|------|
| Mild | 23 | 12 | 23 | 1 43 | 201 |
| Moderate | 10 | 17 | 11 | 76 | 114 |
| 5evere | 6 | 4 | 3 | 40 | 53 |
| Fatal | 1 | 0 | 2 | 52 | 55 |
| Tatal | 40 | 33 | 39 | 311 | 423 |

Four hundred and sixty-six of the 582 cases were bacteriologically confirmed. One hundred and eighty-seven (40 percent) were typed by strain, as shown in Table III. Of the 301 strains tested for toxigenicity, 17 (6 percent) were non-toxigenic.

Table III - Type of Strain Isalated in 1967

| Mitis | 115 |

| Indeterminate | 14 |
| Tatal | 187 |

SUMMARY OF DEATHS AMONG PERSONS 65 YEARS AND OVER IN 108 U.S. CITIES

The weekly average number of deaths among persons 65 years and over in 108 cities for the four-week period ending August 11 was 5,716 as compared with an expected 5,795 weekly average.

| | | WEEK | ENDING | | 4 Week | Weekly |
|----------|-------|-------|--------|-------|--------|---------|

EPIDEMIOLOGICAL REPORT

Paralytic Shellfish Poisoning from Oysters - Colifornia

The first incident in California of shellfish intoxication following the ingestion of oysters has been reported by the California Department of Public Health.

Four residents of Solano County became ill on August 1 with tingling of the lips, numbness of the extremities, muscular incoordination and difficulty in walking. They had consumed raw oysters purchased the same day from a restaurant on the coast about 50 miles north of San Francisco. The oysters had been harvested from a commercial oyster bed in Drakes Bay, Marin County.

Samples of the oysters were examined by the California State Department of Public Health, Division of Laboratories, on August 3 and were found to contain 9600 mouse units of toxin per 100 grams, or approximately 24 times the maximum safe level of 400 mouse units per 100 grams. (Levels as low as 2400 mouse units per 100 grams have on occasion proved lethal to humans.)

The Health Department prohibited further shipments of oysters from the incriminated bed and all oysters from this bed which had been distributed commercially were recalled. Oysters from nearby Tomales Bay showed toxicity levels of nearly 200 mouse units, somewhat below the symptom-causing quantity. Oysters obtained from other nearby beds showed no toxin.

The toxicity of shellfish on the West Coast usually arises as a result of their consumption of Gonyaulax cantanella, a microscopic unicellular plankton organism. These organisms are sometimes present during the summer months in large numbers and may impart a deep rust color to the sea, the so-called "red tide." A quarantine order is issued annually by the California Health Department prohibiting the sale of mussels and warning against eating the dark meat of clams during the period, May 1 to October 31. Ordinarily, shellfish in bays and estuaries, such as oysters, are less affected by the organism than are those on the open shoreline.

Oysters were first incriminated in outbreaks of shellfish poisoning in British Columbia in 1957 where 34 of 61 cases were attributed to oyster consumption.

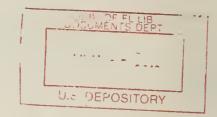

Since first recognition of the problem of paralytic shellfish poisoning in 1793, about 800 cases and 175 deaths have been recorded in various parts of the world. Principally involved have been mussels and soft-shelled clams. Most cases have been reported from the West Coast including California, Oregon, Washington, British Columbia and Alaska. Smaller outbreaks have been recorded in Nova Scotia, New Brunswick, Quebec and Maine.

(Reported by Dr. Vernon B. Link, Head, General Epidemiology Section, California Department of Public Health.)
